CS 2130: Computer Systems and Organization 1 October 15, 2025

#### **Announcements**

- Homework 5 available today, due Monday at 11:59pm on Gradescope
- Fxam 1 scores released

### **Assembly**

#### General principle of all assembly languages

- · Code (text, not binary!)
- 1 line of code = 1 machine instruction
- · One-to-one reversible mapping between binary and assembly
  - We do not need to remember binary encodings!
  - A program will turn text to binary for us!

### **Assembly**

#### Features of assembly

- Automatic addresses use labels to keep track of addresses
  - Assembler will remember location of labels and use where appropriate
  - Labels will not exist in machine code
- Metadata data about data
  - Data that helps turn assembly into code the machine can use
- As complicated as machine instructions
  - There are a lot of instructions, and it is one-to-one!

### **Assembly Languages**

There are many assembly languages

- · But, they're backed by hardware!
- Two big ones these days: x86-64 and ARM
  - You likely have machines that use one of these
- Others: RISC-V, MIPS, ...

We will focus on x86-64

### AT&T x86-84 Assembly

#### instruction source, destination

- Instruction followed by 0 or more operands (arguments)
- · 4 types of operands:
  - Number (immediate value): \$0x123
  - Register: %rax
  - Address of memory: (%rax) or 24 or labelname
  - Value at an address in memory: (%rax) or 24 or labelname

### AT&T x86-84 Assembly

#### mylabelname:

- · Label remember the address of next thing to use later
- .something something
  - Metadirective extra information that is not code
  - How the code works with other things (i.e., talk to OS)
  - Ex: .globl main

```
// we can have comments!
```

# **Addressing Memory**

#### 2130(%rax, %rsp, 8)

- · Address can have up to 4 parts: 2 numbers, 2 registers
- Combines as: 2130 + %rax + (%rsp \* 8)
- · Common usage from this example:
  - rax address of an object in memory
  - 2130 offset of an array into the object
  - rsp index into the array
  - **-** 8 size of the values in the array
- Don't need all parts: (%rax) or (%rax, 4) or 4(%rax)
- This is all one operand (one memory address)

# hello.s example

# Registers

rax is a 64-bit register

### **Instructions**

Instructions have different versions depending on number of bits to use

- · movq 64-bit move
  - q = quad word
- · movl 32-bit move
  - 1 = long
- There are encodings for shorter things, but we will mostly see 32- and 64-bit

### More powerful than our ISA

Instructions can move/operate between memory and register

- · movq %rax, %rcx register to register
  - Remember our icode o
- movq (%rax), %rcx memory to register
  - Remember our icode 3
- · movq %rax, (%rcx) register to memory
  - Remember our icode 4
- · movq \$21, %rax Immediate to register
  - Remember our icode 6 (b=o)

Note: at most one memory address per instruction

#### Other Instructions

Other instructions work the same way

- · addq %rax, %rcx rcx += rax
- subq (%rbx), %rax rax -= M[rbx]
- · xor, and, and others work the same way!
- Assembly has virtually no 3-argument instructions
  - All will be modifying something (i.e., +=, &=, ...)

### **Load Effective Address**

Load effective address: leaq 4(%rcx), %rax

- Performs memory address calculation
- · Stores address, not value at the address in memory

### Jumps

#### jmp foo

- Unconditional jump to foo
- foo is a label or memory address
- Need jmp\* to use register value

#### Conditional jumps

·jl, jle, je, jne, jg, jge, ja, jb, js, jo

Unlike our Toy ISA, these do not compare given register to 0

### **Jumps**

**Condition codes** - 4 1-bit registers set by every math operation, cmp, and test

- Result for the operation compared to 0 (if no overflow)
- Example:
   addq \$-5, %rax
   // ...code that doesn't set condition codes...
   je foo
  - Sets condition codes from doing math (subtract 5 from rax)
  - Tells whether result was positive, negative, 0, if there was overflow, ...
  - Then jump if the result of operation should have been = 0

### Jumps: compare...

```
cmpq %rax, %rdx
```

- Compare checks result of -= and sets condition codes
- · How rdx rax compares with o
- · Be aware of ordering!
  - if rax is bigger, sets < flag
  - if rdx is bigger, sets > flag

# Jumps: ... and test

testq %rax, %rdx

- Sets the condition codes based on rdx & rax
- Less common

Neither save their result, just set condition codes!

### **Example: Loops**

```
while (i < 10)
i += 1
```

### **Functions**

```
f(x,y):
...
return 4
```

```
z = f(2,5)
```

# **Function Calls: Calling Conventions**

#### callq myfun

- · Push return address, then jump to myfun
- · Convention: Store arguments in registers and stack before call
  - First 6 arguments (in order): rdi, rsi, rdx, rcx, r8, r9
  - If more arguments, pushed onto stack (last to first)

#### retq

- Pop return address from stack and jump back
- · Convention: store return value in rax before calling retq

This is similar to our Toy ISA's function calls in homework 4

# Calling Conventions: Registers

#### **Calling conventions** - recommendations for making function calls

- · Where to put arguments/parameters for the function call?
- · Where to put return value? in rax before calling retq
- What happens to values in the registers?
  - Callee-save The function should ensure the values in these registers are unchanged when the function returns
    - \* rbx, rsp, rbp, r12, r13, r14, r15
  - Caller-save Before making a function call, save the value, since the function may change it

#### **Most Common Instructions**

- mov =
- lea load effective address
- · call push PC and jump to address
- add +=
- · cmp set flags as if performing subtract
- · jmp unconditional jump
- · test set flags as if performing &
- je jump iff flags indicate == 0
- pop pop value from stack
- push push value onto stack
- ret pop PC from the stack

example.s

### Debugger

Debugger - step through code!

- You will be using this for lab 7
- Experience seeing results of these instructions step-by-step
- · Please read the x86-64 summary reading before lab!
